Fig. 1. Block coordinate descent method for solving the optimization problem (1) (the iterative process is shown in Fig. 1). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

scattered data fitting problems [30,31]. Data points are scattered over the domain. In this paper, we propose a new iterative algorithm for solving scattered data fitting problems. The proposed algorithm is based on the alternating direction method of multipliers (ADMM) [32–34].

2.2. Kernel regression based on scattered data

In scattered data fitting problems [30,31], it is assumed that the function $T(\cdot)$ is a smooth function. The scattered data points are represented by $(y_i, x_i)_{i=1}^P$, where y_i is the observed value at point x_i . The error term $\varepsilon_i = \varepsilon(x_i)$ is assumed to be zero. The function $T(\cdot)$ is defined as follows:

$$y_i = T(x_i) + \varepsilon_i, \quad x_i \in \Omega, \quad i = 1, \dots, P \quad (3)$$

The scattered data fitting problem (3) can be written as follows: $\min_{T(\cdot)} \|T(\cdot) - y\|_2^2 + \lambda \|T'(\cdot)\|_2^2$, where λ is a regularization parameter. This is a convex optimization problem. The solution can be obtained by the gradient descent method.

The scattered data fitting problem (3) can be solved by the alternating direction method of multipliers (ADMM) [32–34]. The ADMM algorithm consists of two steps: the first step is to solve the subproblem for $T(\cdot)$ and the second step is to update the dual variable λ .

$$\begin{aligned} T(x_i) &\approx T(x) + (\nabla T(x))^T(x_i - x) + \frac{1}{2}(x_i - x)^T \{\text{Hess } T(x)\}^T \\ &\quad \times (x_i - x) + \dots \approx \beta_0 + \beta_1^T(x_i - x) + \beta_2^T((x_i - x)(x_i - x)^T) + \dots \end{aligned} \quad (4)$$

where $\{\beta_0, \beta_1, \beta_2, \dots, \beta_N\}$ are the estimated parameters. As the 2D case, $x = [x_1, x_2]^T$, the equations are as follows:

$$\beta_0 = T(x)$$

$$\beta_1 = \left[\frac{\partial T(x)}{\partial x_1}, \frac{\partial T(x)}{\partial x_2} \right]^T \quad (5)$$

$$\beta_2 = \frac{1}{2} \left[\frac{\partial^2 T(x)}{\partial x_1^2}, \frac{\partial^2 T(x)}{\partial x_1 \partial x_2}, \frac{\partial^2 T(x)}{\partial x_2^2} \right]^T$$

...

$$\begin{aligned} S &= \sum_{i=1}^P [y_i - \beta_0 - \beta_1^T(x_i - x) - \dots]^2 K_H(x_i - x) \\ &= \sum_{i=1}^P [y_i - \beta_n - \beta_{n+1}^T(x_i - x) - \dots]^2 K_H(x_i - x) \end{aligned} \quad (6)$$

where $K_H(\cdot)$ is a kernel function (see the definition of $K_H(\cdot)$), β_n is the solution of the subproblem (3), and β_{n+1} is the updated solution.

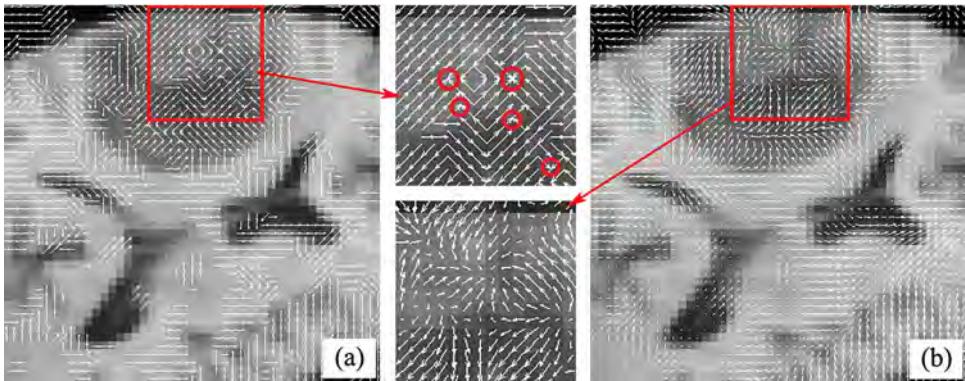

Fig. 2. A comparison of the surface morphology between two samples. (a) The sample has a relatively smooth surface with some small pits. (b) The sample has a more pronounced and irregular surface texture.

and the surface roughness is 2D case

$$\sigma_u(x_0) = \frac{1}{2\pi\sigma_u\sigma_v} e^{-\left(\frac{d_u^2}{2\sigma_u^2} + \frac{d_v^2}{2\sigma_v^2}\right)} \quad (13)$$

$$d_u = \langle d, u \rangle, \quad d_v = \langle d, v \rangle, \quad d = x - x_0$$

where x_0 is the center position, $\{d_u, d_v\}$ are the unit vectors of the surface normal, and $\{\sigma_u, \sigma_v\}$ are the standard deviations of the surface height along the two directions.

$$\sigma_u = \frac{\alpha}{\alpha+A} \sigma_c, \quad \sigma_v = \frac{\alpha+A}{\alpha} \sigma_c \quad (14)$$

where $A = (\lambda_u - \lambda_v)/(\lambda_u + \lambda_v)$. The value of A is approximately 0.5. The values of σ_c and σ_u are 1.5 and 0.5, respectively. The value of σ_v is calculated to be 0.75. The surface height distribution is a Gaussian function with a standard deviation of 0.75. The size of the simulation domain is 3×3 .

The simulation results show that the surface roughness is significantly reduced at the early stages of the process. At the later stages, the surface becomes smoother and more uniform. This is due to the fact that the surface height distribution is a Gaussian function, which is centered around zero. As the process continues, the standard deviation of the surface height distribution decreases, resulting in a smoother surface.

Fig. 4 shows the simulation results for the surface roughness at different stages of the process. The simulation results show that the surface roughness is significantly reduced at the early stages of the process. At the later stages, the surface becomes smoother and more uniform. This is due to the fact that the surface height distribution is a Gaussian function, which is centered around zero. As the process continues, the standard deviation of the surface height distribution decreases, resulting in a smoother surface.

As the process continues, the standard deviation of the surface height distribution decreases, resulting in a smoother surface.

Fig. 4(g).

2.4. Relying on imaging JSM

The imaging JSM was used to measure the surface roughness of the samples. The samples were prepared by the same method as the simulation samples. The surface roughness was measured at different stages of the process. The results are shown in Fig. 4. The surface roughness is significantly reduced at the early stages of the process. At the later stages, the surface becomes smoother and more uniform. This is due to the fact that the surface height distribution is a Gaussian function, which is centered around zero. As the process continues, the standard deviation of the surface height distribution decreases, resulting in a smoother surface.

The imaging JSM was used to measure the surface roughness of the samples. The samples were prepared by the same method as the simulation samples. Fig. 11. Microstructure evolution process of Ni₃Al₂O₃ composite at different temperatures. (a) 1000 °C, (b) 1100 °C, (c) 1200 °C, (d) 1300 °C, (e) 1400 °C, (f) 1500 °C, (g) 1600 °C.

The microstructure evolution process of Ni₃Al₂O₃ composite at different temperatures is shown in Fig. 11. At 1000 °C, the primary phase is a eutectic structure of Ni₃Al and Al₂O₃. As the temperature increases to 1100 °C, the size of the primary phase increases significantly. At 1200 °C, the primary phase becomes larger and more irregular. At 1300 °C, the primary phase has almost completely disappeared, and the secondary phase has grown into large grains. At 1400 °C, the secondary phase has grown into even larger grains. At 1500 °C, the secondary phase has grown into very large grains. At 1600 °C, the secondary phase has grown into extremely large grains, indicating that the composite has undergone significant structural transformation.
